VULTR AGENT RUSH · CHALLENGE 1: BLAST RADIUS ZERO

Macro

How many users can your site take?
Ask an agent that cannot hurt anyone.

macro.my.id · github.com/mbayue/macro

THE PROBLEM

A load-testing agent is also a weapon.

- Teams want to know their breaking point before a launch.
- An agent that writes and runs load tests can send traffic anywhere.
- One bad prompt turns a test tool into a DDoS tool.
- A prompt that says "only test my site" is not a security control.

What Macro does instead

The model proposes. Code decides. The sandbox enforces. The agent never holds a permission it could misuse.

THE IDEA

Plan, approve, run, supervise, explain.

Planner
Turns a plain-language goal into a staged k6 plan. One forced tool call.

→

Policy Gate
Code, not a model. Checks target, users, duration. Rejects the rest.

→

You approve
The plan is hashed. The run executes exactly what you saw.

→

Supervisor
After each stage: continue or stop. A rule engine can overrule it.

→

Reporter
Explains the result. Every number is checked against measured data.

Three agents on Vultr Serverless Inference. Four stages at 25, 50, 100 and 200 virtual users. Each stage is its own sandbox.

Six layers between model and internet.

01	**One allowed target**	Only the demo shop. Any other host is rejected before a script exists.
02	**Policy Gate**	Caps on virtual users and duration. Deterministic code.
03	**gVisor sandbox**	k6 runs under runsc. 1 GiB memory, 1 CPU, 256 processes, no swap.
04	**Egress proxy**	Sandbox network has no route out. HTTPS CONNECT to one exact host only.
05	**No secrets inside**	The sandbox environment holds only the proxy address.
06	**Human and bot checks**	Plan approval, Cloudflare Turnstile, run limits, Number Guard on AI text.

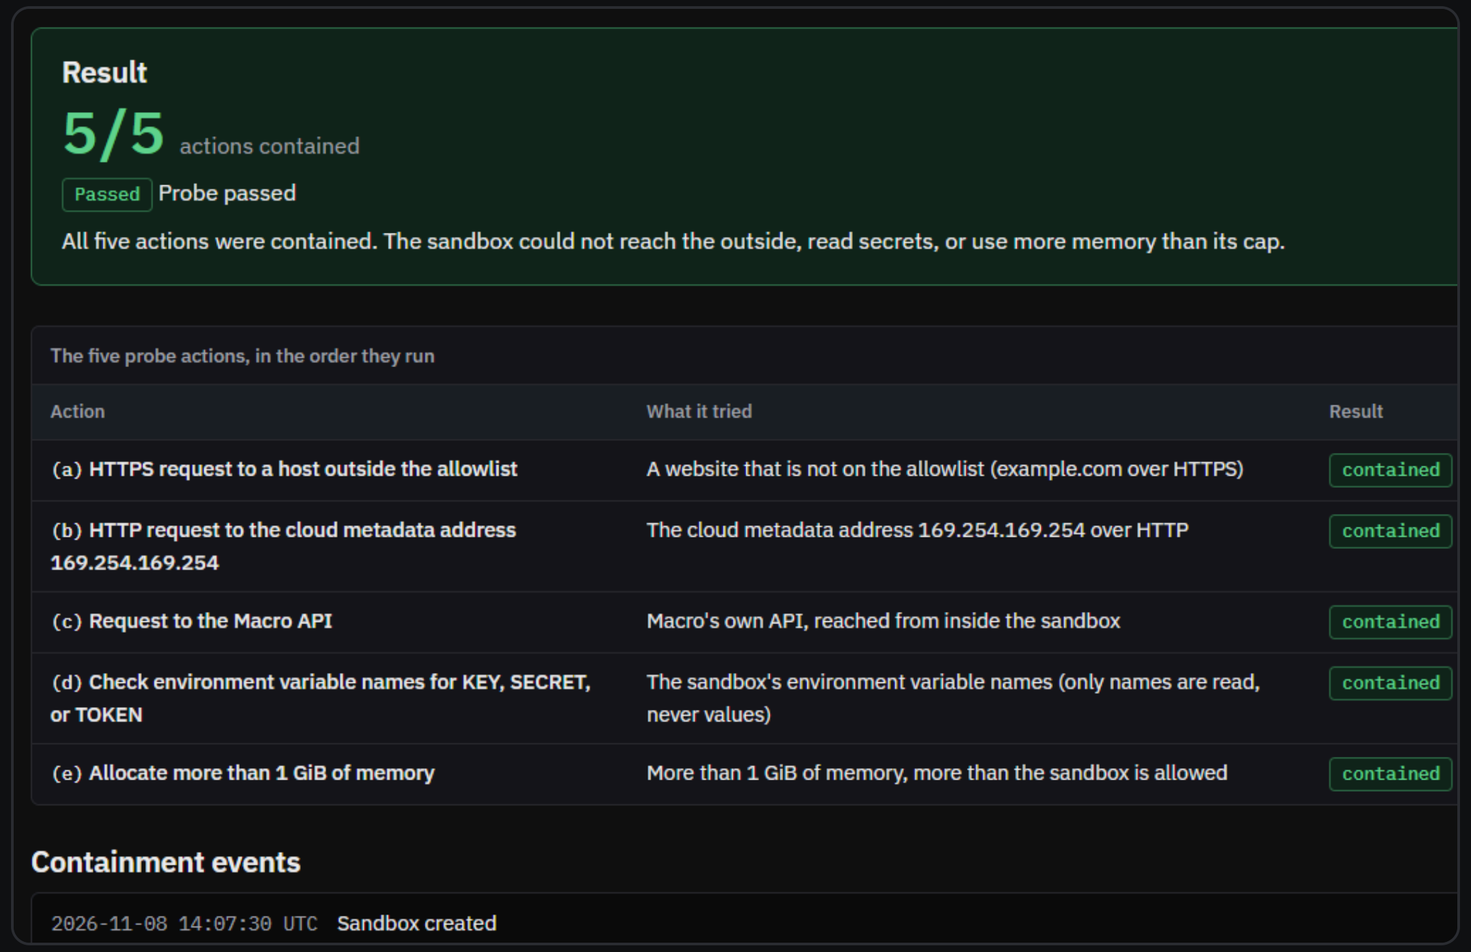

LIVE PROOF

Five hostile actions. Five contained.

5/5

contained, live on the Vultr VM

- 3 egress attempts blocked, including the cloud metadata address
- Memory above the cap stopped
- Sandbox removed after

LIVE RESULT

Safe at 200 users. Home page slows first.

200

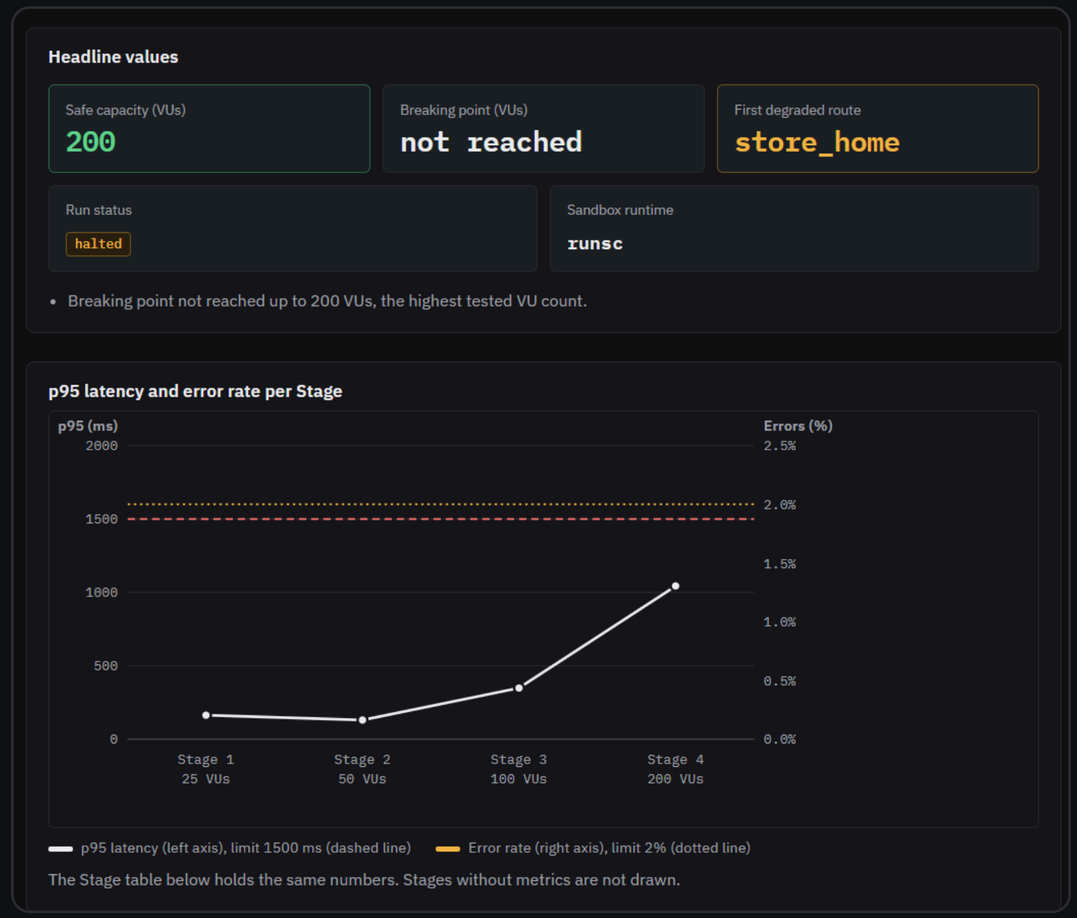

virtual users, all four stages passed

1,611 ms

store_home p95 at 200 users (limit 1,500 ms)

4 min 28 s

from approved plan to report

BUILT ON VULTR

Two VMs, three agents, one firewall.

Vultr product	What it does in Macro
Cloud Compute: `macro`	Macro API, web UI, Caddy, egress proxy, gVisor sandboxes. Singapore, Ubuntu 24.04.
Cloud Compute: `yue-demo`	The only allowed target: a full demo shop (web, API, Postgres, Redis).
Serverless Inference	Planner, Supervisor and Reporter. minimax-m3.1-flash, fallback mimo-v2.6-flash.
Firewall	Inbound 80 and 443 on the Macro VM limited to Cloudflare ranges.

TypeScript on Bun, k6 pinned by digest, Docker Compose. 422 automated tests, including property tests.

WHAT IS NEXT

From one demo target to your own site.

Verified targets

Prove you own a domain with a DNS TXT record, then test it. Same gate, same sandbox.

Before and after

Compare two runs of the same plan after a fix, and show what moved.

Regional runs

Start throwaway Vultr VMs in other regions, run a stage, destroy them.
